## **Problem Statement:**

In current World where people are addicted to their screens and as it is almost impossible for them to get out of screen and live in real world. Doom scrolling has become very normal and it is brain rotting everyone around. People have loose their

basic ability of being innovative, creative and thin critically. I was motivated to solve this particular issue but by providing something as engaging yet is comparatively productive. I being avid reader my self had faced problems in finding

a good book in genre that i am interested in, mailing authors was one option but getting reply was uncertain so that's why i had though making social media for book

lovers where functionality like being in touch with authors knowing about their interest and motivation to write the book exploring new books in market, interaction

with author and attending book talks is are features i was looking for.

## **Objectives:**

1. Develop a Role-Based System: To design, develop, and implement a secure, role-based authentication system for two distinct user types, "Author" and "Reader," within the first two months of the project.

2. Implement Core Author Features: To build and deploy the three core content creation features for Authors (Publish Book, Announcement, Book Talk) with full backend integration to Firestore within the first three months.

3. Establish Reader Engagement Loop: To develop the reader-side features for content discovery, following authors, and interaction (liking/commenting) by the end of the project, aiming to achieve a functional prototype for user testing.

4. Launch a Minimum Viable Product (MVP): To deliver a stable, cross-platform mobile application on Android that successfully connects at least one author and one reader, demonstrating the complete content lifecycle from creation to consumption.

### **Relevance to ICT Domain:**

This project is firmly rooted in the modern ICT domain of cross-platform mobile application development. The solution is built using Google's Flutter framework, chosen for its ability to create a single, high-performance codebase that runs natively

on both Android and iOS. The backend architecture leverages Google's Firebase, a comprehensive

Backend-as-a-Service (BaaS) platform. This includes:

- **Firestore Database:** A NoSQL database used to store all structured data, such as user profiles (with their roles), book details, announcements, and content metadata.
- **Firebase Storage:** Used to store large, unstructured files, specifically the book cover images and other media uploaded by authors.
- **Firebase Authentication:** Handles the entire user management lifecycle, including secure sign-in/signup with email, password, and Google Sign-In.
- **Firestore Security Rules:** Custom rules have been written to define access permissions, ensuring that authors can only manage their own content while allowing readers to view public posts, thus securing the platform.
- **Cloud Firestore Indexing:** To ensure fast and efficient data retrieval for features like the "My Content" feed (sorting by date), composite indexes have been configured in Firebase.

### **Feasibility Analysis:**

- **Technical Feasibility:** The project is technically sound. It is built using Flutter, a modern framework based on the Dart programming language, which is well-documented with a strong community. The development environment relies on standard, freely available tools like Android Studio and the Flutter SDK. The chosen backend, Firebase, provides robust SDKs that integrate seamlessly with Flutter, making the development of complex features like real-time data streaming and authentication achievable.
- **Economic Feasibility:** The project is highly cost-effective. The primary development tools (Flutter, Android Studio, Dart) are open-source and free. The backend hosting with Firebase operates on a generous free tier (the "Spark Plan"), which is more than sufficient for development and small-scale user testing. The app is designed to scale using Firebase's pay-as-you-go "Blaze Plan," which is economically feasible as costs would only increase with a growing user base. No other significant capital investment is required.
- **Ethical Considerations:** The app prioritizes user data security. All user data is stored on Google's secure Firebase platform, which employs high-level encryption. The app is designed to avoid collecting sensitive personal information, and since there are no financial transactions, the risk of financial fraud is eliminated. Future considerations would involve creating a clear content moderation policy to ensure a safe and positive community environment.

### **Market/User Needs Analysis & Novelty**

**Market Analysis & Novelty:** While the book-lover market has several established platforms, "Bibliophilic" addresses a clear gap. Competitors like Goodreads excel at cataloging and reviews but function more as a database than a dynamic community. Other platforms like Book Club or LibraryThing focus on community meetings or cataloging personal libraries, respectively. The novelty of Bibliophilic lies in its core mission: to create a direct, dynamic, and engaging social link between authors and readers. Unlike existing solutions,

this platform is not just about tracking what you've read; it's about being part of the creative journey. The key differentiating features that meet this user need are:

- The Author-Centric Feed: Readers receive a personalized feed of content directly from the authors they choose to follow.
- Direct Interaction: The platform facilitates direct reviews, likes, and comments on an author's page, fostering a closer relationship.
- Integrated Experience: By combining book publishing, announcements, and live event scheduling into one unified feed, the app makes the reading habit feel more interactive and addictive, providing a productive and enriching alternative to passive social media consumption
